

PopcornSwirl App

<https://github.com/Ra-Fa-L/OC-06-PopcornSwirl>

For PopcornSwirl project following technical requirements were created:

- A screen with latest movies loaded from a online movie database
- If user clicks one of the chosen movies, he will be provided with a extra detail screen of the selected movie
- A user can bookmark a movie to form their personal selection, mark it as "watched", and add a note.
- A user can view the bookmarked list and the list of "watched" movies
- While a user is viewing details of a particular movie, they are presented with related information that may interest them

Based on those requirements I have decided to use:

- [themoviedb.org](https://www.themoviedb.org) movies database as a online databank
- CoreData as a storage library for bookmarked movies
- TabBarController will be used to make 3 screen quickly accessible for the user

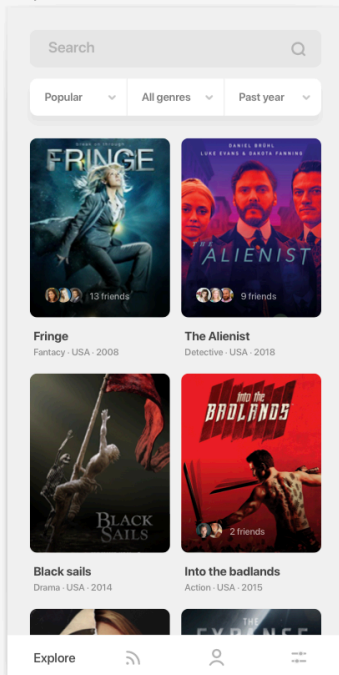

Additionally some others decisions has been made for projects implementation:

- Newly added SwiftUI framework will be heavily used as a additional challenge
- Additional screen with possibility to search movies by the title

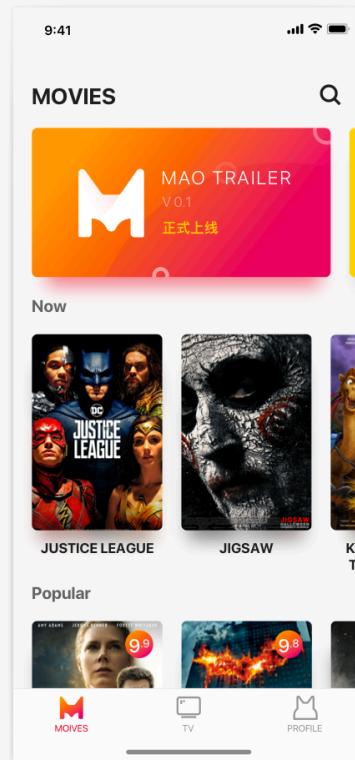

And many other extra addition has been made to provide the app with more professional look and feel.

The Design of the app will be created based on some free online sketch designs with custom implementations and some own ideas.
